

Answer **THREE** questions.

The numbers in square brackets in the right-hand margin indicate the provisional allocation of marks for each subsection of a question.

Question 1

- a) Show that if linearly polarised light is incident on a polariser such that the angle between the plane of polarisation of the light and the transmission axis of the polariser is θ , the fraction of the incident intensity that is transmitted is $\cos^2 \theta$. [3]
- b) If the light incident on the polariser in a) is unpolarised rather than linearly polarised, what fraction of the intensity is transmitted? [3]
- c) What is meant by a *half-wave plate*? [4]
- d) Show that if linearly polarised light is incident on a half-wave plate such that the plane of polarisation of the light makes an angle θ with the fast-axis of the wave-plate, the plane of polarisation of the light emerging from the wave-plate is rotated through an angle of magnitude 2θ . [5]
- e) A half-wave plate is placed, as shown in the figure, between a crossed polariser and analyser such that the angle between the polariser transmission axis and the fast axis of the half-wave plate is θ .

If the light incident on the polariser from the left is unpolarised and has intensity I_0 , show that the intensity of the light emerging to the right of the analyser is

$$I = \frac{I_0}{4} (1 - \cos 4\theta). \quad [5]$$

(you may assume the identity $\cos 2x = 1 - 2 \sin^2 x$).

Question 2

- a) Show, detailing the approximations used, how the spherical-wave solution to the wave-equation can be modified to describe a propagating Gaussian-beam and hence show that the spot-size $w(z)$ a distance z from the beam-waist is given by

$$w^2(z) = w_0^2 \left(1 + \frac{z^2}{z_R^2} \right).$$

Show that $z_R = \frac{\pi w_0^2}{\lambda}$ where λ is the wavelength of the light and describe the physical significance of w_0 and z_R .

[10]

- b) State the ABCD law of Gaussian-beams.

[2]

- c) A Gaussian-beam of wavelength $\lambda = 628 \text{ nm}$ and waist $w_1 = 1 \text{ cm}$ is focused, as is shown in the figure, by a thin, positive lens of focal length $f = 5 \text{ cm}$ placed a distance $z_1 = 5.25 \text{ cm}$ beyond the waist, to form a new waist of spot size w_2 a distance z_2 beyond the lens.

By finding the ray transfer matrix describing the propagation of the beam between the waists and applying the ABCD law, determine w_2 and z_2 .

[8]

{ You may assume the following ray transfer matrices:

for translation through a distance d : $\begin{pmatrix} 1 & d \\ 0 & 1 \end{pmatrix}$

for a thin-lens of focal length f : $\begin{pmatrix} 1 & 0 \\ -\frac{1}{f} & 1 \end{pmatrix}$ }

Question 3

- a) Describe, with reference to a suitable energy-level diagram, how a population inversion is achieved in a helium-neon laser. [6]
- b) What is meant by the *brightness* of a light source? [2]
- c) A helium-neon laser designed to produce 1mW of optical power at a wavelength of 632 nm has a cavity length of 30 cm. The active medium, which can be assumed to occupy the entire laser cavity has a gain coefficient of $2.5\% \text{ m}^{-1}$ whilst the intra-cavity losses are equivalent to a loss coefficient of $1\% \text{ m}^{-1}$. The gain profile has a Doppler-broadened width, at the threshold gain, of 1 GHz and the intra-cavity waist size is 0.5mm.
- i. Find the frequency separation of the longitudinal cavity modes and hence the number of modes that will oscillate when laser action occurs. [3]
- ii. Explain, giving reasons, how your answer to i. would differ if the laser transition were *homogeneously broadened*. [3]
- iii. If one cavity mirror has a reflectivity of 100%, find the maximum value of the transmission coefficient of the other cavity mirror for lasing action to be possible. [3]
- iv. Calculate the brightness of the helium-neon laser, assuming that the full-angle divergence of the beam is given by $\theta = \frac{2\lambda}{\pi w_0}$ where w_0 is the intra-cavity waist size. [3]

Question 4

a) State the conditions under which a 2x2 ray transfer matrix can be used to describe an optical system. [2]

b) An optical system has a transfer matrix $\begin{pmatrix} A & B \\ C & D \end{pmatrix}$. Describe, with the aid of suitable diagrams, the effect of the system if

- i. $B = 0$
- ii. $C = 0$.

[5]

c) An optical system occupies the region of space $0 < z \leq z_0$. In this region, the ray transfer matrix is

$$\begin{pmatrix} -2 & z/2 \\ 0 & a \end{pmatrix}$$

i. Show that if the refractive index in the regions $z \leq 0$ and $z \geq z_0$ is $n = 1$ then

$$a = -\frac{1}{2}.$$

[2]

ii. By considering the ray transfer matrix in the region $z > z_0$, find the location and magnification of the image of an object placed at $z=0$.

[5]

d) Show that the ray transfer matrix of a thin lens of focal-length f is

$$\begin{pmatrix} 1 & 0 \\ -\frac{1}{f} & 1 \end{pmatrix}.$$

[3]

Hence show that the focal-length of a stack of N thin lenses, each of focal-length f , is $\frac{f}{N}$.

[3]

{ You may assume that the ray transfer matrix for translation through a distance d is

$$\begin{pmatrix} 1 & d \\ 0 & 1 \end{pmatrix} \}$$

Question 5

- a) Define the *Einstein coefficients* A_{21} , B_{21} and B_{12} for radiative transitions between an upper level 2 and a lower level 1 of an atom.

Show that the B-coefficients satisfy $g_2 B_{21} = g_1 B_{12}$ where g_1 and g_2 are the degeneracies of the levels.

[7]

- b) A model atom has three levels with energies $E_3 > E_2 > E_1$ and $g_2 = g_3 = 1$. Levels 2 and 3 are populated by unspecified processes at rates per unit volume R_2 and R_3 respectively. Spontaneous emission occurs between levels 3 and 2 and between levels 2 and 1 only.

- i. Write down suitable rate-equations governing the time evolution of the populations of the atomic energy levels and hence derive an expression for the steady-state value of $N_3 - N_2$ (you may assume that stimulated emission and absorption on the transition between levels 1 and 2 can be neglected).

[8]

- ii. What condition must $N_3 - N_2$ satisfy for laser action to be possible on the transition between levels 3 and 2 ?

[1]

- iii. Hence show that for laser action to be possible, the pumping rates must satisfy

$$\frac{R_3}{R_2} > \frac{A_{32}}{A_{21} - A_{32}}.$$

[2]

- iv. In addition to the pumping of levels 2 and 3, the atom is now subjected to radiation at a frequency $\nu_{32} \equiv (E_3 - E_2)/h$ with an energy density $\rho(\nu_{32}) = 0.25 \frac{A_{32}}{B_{32}}$. Find the percentage change in the population difference $N_3 - N_2$ that results.

[2]
